2021121006

1. → States : Possible states of can be various permutations of blocks and block stacks on the table.
eg. $[A, B, C]$, $[B, C, A]$
- actions : An action is to take a block that is not ~~on~~ under another and move it to a new location.
- Initial state can be any of the possible states.
eg. $\begin{bmatrix} A & C \\ B & D \end{bmatrix}$
- goal test : For example testing the goal state for $s = [A, B]$ can be
 $S[0] == A$ and $S[1] == B$
- Path cost : Every action can be assigned a cost of K .

2. Initial state = $\begin{bmatrix} C & B \\ A & \end{bmatrix}$

final state = $\begin{bmatrix} A & B \\ C & \end{bmatrix}$

// assuming the table is only wide enough for 3 blocks.

Iteration 1

$\begin{bmatrix} C & A & B, A & \overset{C}{B}, \overset{B}{A} \end{bmatrix}$

Iter 2:

$\begin{bmatrix} \overset{B}{A}, \overset{C}{A}, \overset{B}{B}, \overset{C}{A}, \overset{A}{B}, \overset{B}{C}, \overset{A}{C}, \overset{B}{A}, \overset{B}{C}, \overset{A}{B}, \overset{B}{C}, \overset{A}{B} \end{bmatrix}$

Iter 3

$\begin{bmatrix} A & \overset{C}{B}, \overset{C}{A}, \overset{A}{B}, \overset{A}{C}, \overset{B}{C}, \overset{B}{A}, \overset{B}{C} \end{bmatrix}$

DFS

Iteration

1: $\begin{bmatrix} C & A & B, A & \overset{B}{C}, \overset{C}{A}, \overset{B}{B} \end{bmatrix}$

2: 4

2: $\begin{bmatrix} \overset{C}{A}, \overset{B}{B}, \overset{C}{A}, \overset{B}{B}, \overset{A}{C}, \overset{A}{B}, \overset{B}{C}, \overset{B}{C}, \overset{A}{B}, \overset{B}{C}, \overset{A}{B}, \overset{B}{C} \end{bmatrix}$

3: $\begin{bmatrix} C & A & B, A & B & C, A & \overset{B}{C}, \overset{A}{B}, \overset{A}{C}, \overset{B}{B}, \overset{B}{C}, \overset{A}{B}, \overset{B}{C} \end{bmatrix}$

Uniform Cost

iteration:

1: $\begin{bmatrix} C & A & B, A & \overset{C}{B}, \overset{B}{A} \end{bmatrix}$

2: $\begin{bmatrix} \overset{B}{A}, \overset{C}{A}, \overset{B}{B}, \overset{C}{A}, \overset{A}{B}, \overset{B}{C}, \overset{A}{C}, \overset{B}{A}, \overset{B}{C}, \overset{A}{B}, \overset{B}{C}, \overset{A}{B} \end{bmatrix}$

3: $\begin{bmatrix} A & \overset{C}{B}, \overset{C}{A}, \overset{A}{B}, \overset{A}{C}, \overset{B}{C}, \overset{B}{A}, \overset{B}{C} \end{bmatrix}$

3. \rightarrow One possible heuristic is the measure the ^{absolute} difference in ^{tower} width of the state and goal.

eg. $S = [A \ B \ C]$, goal = $[\begin{smallmatrix} A \\ B \\ C \end{smallmatrix}]$
 width = 3 $\underline{\quad \quad \quad}$ width = 1 $\underline{\quad}$
 $\text{widthDiff}(S) = 13 - 11 = \underline{\underline{2}}$

\rightarrow Another heuristic is to count the number of blocks that are at the wrong height.

eg. $S = [A \ B \ C]$, goal = $[\begin{smallmatrix} A \\ B \\ C \end{smallmatrix}]$
 only ~~A~~ ~~B~~ C is at the right height

$\text{correctHeight}(S) = \underline{\underline{1}}$
